Observer based actuator fault tolerant control for nonlinear Takagi-Sugeno systems: an LMI approach

Dalil Ichalal, Benoît Marx, José Ragot, Didier Maquin

Abstract—A new actuator fault tolerant control strategy is proposed for nonlinear Takagi-Sugeno (T-S) systems. The control law aims to compensate the actuator faults and allows the system states to track a reference corresponding to a fault free situation. The design of such a control law requires the knowledge of the faults, this task is achieved with a proportional integral observer (PIO). The robust stability of the system with the fault tolerant control law is analyzed with the Lyapunov theory and the $L_2$ optimization. Sufficient stability conditions are obtained in terms of linear matrix inequalities (LMIs). The gains of the FTC are obtained by solving these LMIs. A simulation example is finally proposed.

Index Terms—Takagi-Sugeno systems, state and fault estimation, PIO, Lyapunov stability analysis, linear matrix inequality.

I. INTRODUCTION

It is well known that the classical control strategies cannot take into account faults affecting a system. Then, if a fault occurs in any component of the system, the stability and the performances of the system cannot be ensured. These last years, the problem of fault tolerant control design has been treated and many significant results have been proposed in [14], [2], [16], [17]. These works follow two different ideas. The first one, called passive FTC, considers possible fault situations and take them into account in the step of control design; this approach is similar to the robust control design. It is pointed out in many works that this strategy is usually restrictive. The second approach is the active FTC, which requires a fault diagnosis block providing on line informations on fault detection, isolation and estimation. The reconfigurable control block uses these informations in order to deal with unforeseen faults, to maintain the system stability and to provide an acceptable system trajectory even in faulty situations.

The active fault tolerant control has been developed essentially for linear systems [5], [19], [17], [14] and descriptor linear systems [12]. Clearly, linear models do not often represent accurately physical systems due to the presence of nonlinear behavior. A new representation that combines simplicity and accuracy of nonlinear behaviors, introduced initially in [20], was known under the name Takagi-Sugeno (T-S) models. The idea is to consider a set of linear sub-systems. An interpolation of all these sub-models with nonlinear functions satisfying the convex sum property allows to obtain the global behavior of the system described in a large operating range. Some works can be mentioned in the FTC field for nonlinear systems. For example, in [6], the authors took into account actuator faults for nonlinear descriptor systems with Lipschitz nonlinearities. In [18], a method which requires only the fault isolation was proposed for T-S systems. It was based on a bank of observer based controllers. A switching mechanism is then designed depending on the obtained residuals. More recently, Witczak proposed in [23] an FTC strategy based on a reference model for open-loop T-S systems.

This paper is dedicated to the design of a fault tolerant control strategy for nonlinear systems described by Takagi-Sugeno models. This approach is an extension of the work proposed in [23], to T-S systems where the weighting functions are affected by faults. Thus, the premise variables of the reference model are not the same as those of the faulty system. The main idea is to re-use the nominal control input developed in fault-free case for which two terms, related to the occurred fault and the tracking error trajectory between the system and a reference model, are added. The reference trajectory is provided from a reference model representing the system without faults. In addition, the control law requires the knowledge of the state of the system and the faults affecting it. For that purpose, a PIO is used to estimate simultaneously these signals.

A. Takagi-Sugeno structure for modeling

Let us consider a nonlinear system described by a T-S structure

$$
\begin{align*}
\dot{x}(t) &= \sum_{i=1}^{r} \mu_i(\xi(t))(A_i x(t) + B_i u(t)) \\
y(t) &= \sum_{i=1}^{r} \mu_i(\xi(t))C_i x(t)
\end{align*}
$$

(1)

where $x(t) \in \mathbb{R}^n$ is the state vector, $u(t) \in \mathbb{R}^m$ is the input vector, and $y(t) \in \mathbb{R}^p$ represents the output vector. $A_i \in \mathbb{R}^{n \times n}$, $B_i \in \mathbb{R}^{n \times m}$, $C_i \in \mathbb{R}^{p \times n}$ and $D_i \in \mathbb{R}^{p \times m}$ are known matrices. The functions $\mu_i(\xi(t))$ are the weighting functions depending on the variables $\xi(t)$ which can be measurable (as the input or the output of the system) or non measurable variables (as the state of the system). These functions verify the following properties

$$
\begin{align*}
\sum_{i=1}^{r} \mu_i(\xi(t)) &= 1 \\
0 \leq \mu_i(\xi(t)) \leq 1 & \forall i \in \{1,2,...,r\}
\end{align*}
$$

(2)

Obtaining a T-S model (1) can be performed from different methods such as linearization of a nonlinear model...
B. Notations and preliminaries

Let us consider the matrix \( Y_{ij} \) with appropriate dimension, and \( \mu_r(\cdot) \) nonlinear functions satisfying the convex sum property. The following notation is defined

\[
Y_{\xi \xi} = \sum_{i=1}^{r} \sum_{j=1}^{r} \mu_i(\xi(t))\mu_j(\xi(t))Y_{ij} \tag{3}
\]

**Lemma 1:** [22] The inequality \( Y_{\xi \xi} < 0 \) holds if

\[
\frac{2}{r-1} Y_{ii} + Y_{ij} + Y_{ji} < 0, \quad i, j = 1, \ldots, r, \quad i \neq j \tag{4}
\]

**Lemma 2:** (Congruence) Let two matrices \( P \) and \( Q \), if \( P \) is positive definite and if \( Q \) is a full column rank matrix, then the matrix \( Q^TPQ \) is positive definite.

**Notation 1:** For any square matrix \( M \), \( S(M) \) is defined by:

\[
S = M + M^T \tag{6}
\]

II. FAULT TOLERANT CONTROL OF T-S FUZZY SYSTEMS

A. FTC strategy

Let us consider the T-S reference model without faults described by (1). The faulty system is given by

\[
\begin{cases}
\dot{x}_f(t) = \sum_{i=1}^{r} \mu_i(\xi_f(t))(A_i x_f(t) + B_i (u_f(t) + f(t))) \\
y_f(t) = \sum_{i=1}^{r} \mu_i(\xi_f(t))C_i x_f(t)
\end{cases} \tag{7}
\]

In this paper only additive faults on the form given in (7) are treated, for instance, bias on the input signal. Note that, the weighting functions depend on a faulty premise variable \( \xi_f(t) \). Indeed, if these last are the input of the system, which can depend on the state \( x_f(t) \) in closed-loop, or the output \( y_f(t) \), necessarily the fault affects these variables.

The goal is to design the control law \( u_f(t) \) such that the system state \( x_f(t) \) converges toward the reference state \( x(t) \) given by the reference model (1) whatever the fault \( f(t) \) should be. The control strategy is illustrated in the figure 1.

![Fault tolerant control scheme](image)

We propose the following structure for the control law

\[
u_f(t) = -\hat{f}(t) + K(x(t) - \hat{x}_f(t)) + u(t) \tag{8}
\]

The matrix \( K \) is determined in order to ensure the stability of the system even if faults occur and to minimize the state error between \( x_f(t) \) and \( x(t) \). By analyzing the structure of \( u_f(t) \) given in equation (8), the estimation of the state vector \( x_f(t) \) and faults \( f(t) \) are required. This task is performed via a Proportional-Integral observer simultaneously estimating the state and the faults of the system.

Let us consider the PIO

\[
\begin{align}
\dot{\hat{x}}_f(t) &= \sum_{i=1}^{r} \mu_i(\xi_f(t))(A_i \hat{x}_f(t) + B_i (u_f(t) + \hat{f}(t))) \\
&\quad + H_{1i}(y_f(t) - \hat{y}_f(t)) \tag{9}
\end{align}
\]

\[
\dot{\hat{f}}(t) = \sum_{i=1}^{r} \mu_i(\xi_f(t))(H_{2i}(y_f(t) - \hat{y}_f(t))) \tag{10}
\]

\[
\hat{y}_f(t) = \sum_{i=1}^{r} \mu_i(\xi_f(t))C_i \hat{x}_f(t) \tag{11}
\]

In fact if \( \xi_f(t) \) is assumed to be known, the observer weighting functions depend on the same premise variable as the system (7).

The output error between the system (7) and the observer (9) is written by

\[
y_f(t) - \hat{y}_f(t) = \sum_{i=1}^{r} \mu_i(\xi_f(t))C_i e_a(t) \tag{12}
\]

where

\[
C_i = \begin{bmatrix} C_i & 0 \end{bmatrix} \tag{13}
\]

\[
e_a(t) = x_a(t) - \hat{x}_a(t), \quad x_a(t) = \begin{bmatrix} x_f(t) \\ f(t) \end{bmatrix} \tag{14}
\]
The dynamic of the tracking error $e(t) = x(t) - x_f(t)$, obeys to the differential equation

$$
\dot{e}(t) = \sum_{i=1}^{r} \mu_i(\xi(t))(A_i x(t) + B_i u(t)) - \mu_i(\xi(t))A_i x_f(t) + B_i (u_f(t) + f(t))
$$

(15)

$$
\dot{e}(t) = \sum_{i=1}^{r} \mu_i(\xi(t))(A_i e(t) - B_i (f(t) - \hat{f}(t)) = B_i K (x_f(t) - \hat{x}_f(t)) + \delta(t) + \sum_{i=1}^{r} \mu_i(\xi(t))((A_i - B_i K)e(t) - \tilde{L}_i e_a(t)) + \delta(t)
$$

(16)

(17)

where

$$
\tilde{L}_i = \left( \begin{array}{cc} B_i & K \\ B_i & \end{array} \right)
$$

(18)

(19)

Assume that $\dot{f}(t) = 0$, the system (7) can be written in an augmented form

$$
\begin{align*}
\dot{x}_a(t) &= \sum_{i=1}^{r} \mu_i(\xi(t)) (\tilde{A}_i x_a(t) + \tilde{B}_i u_f(t)) \\
y_f(t) &= \sum_{i=1}^{r} \mu_i(\xi(t))(\tilde{C}_i x_a(t)
\end{align*}
$$

(20)

where

$$
\tilde{A}_i = \left( \begin{array}{cc} A_i & B_i \\ 0 & 0 \end{array} \right), \quad \tilde{B}_i = \left( \begin{array}{c} B_i \\ 0 \end{array} \right)
$$

(21)

The pairs $(\tilde{A}_i, \tilde{C}_j)$, $i, j = 1, \ldots, r$ are assumed to be observable (or at least detectable). The state and fault estimation error $e_a(t) = x_a(t) - \hat{x}_a(t)$ between the system (20) and the observer (9)-(11) evolves following the equation

$$
\dot{e}_a(t) = \sum_{i=1}^{r} \sum_{j=1}^{r} \mu_i(\xi(t)) \mu_j(\xi(t)) (\tilde{A}_{ij} - H_i \tilde{C}_j) e_a(t)
$$

(22)

(23)

where

$$
\begin{align*}
\dot{e}(t) &= \left( x(t) - x_f(t) \quad x_a(t) - \hat{x}_a(t) \right), \quad \tilde{\Gamma} = \left( \begin{array}{cc} I_n & 0 \\ 0 & 0 \end{array} \right) \\
\tilde{A}_{ij} &= \left( \begin{array}{cc} A_i - B_i K & -\tilde{L}_i \\ \tilde{A}_i - H_i \tilde{C}_j \end{array} \right)
\end{align*}
$$

(24)

(25)

Remark 1: One can note that in the previous section, the weighting functions depend on the premise variable $\xi_f(t)$. It can be an external known variable which is not affected by faults. Indeed, in [23], the authors proposed a method for this case with an application to the three tank system in open-loop control. In this case, $\xi(t) = \xi_f(t)$ and the equation (23) becomes

$$
\dot{\tilde{e}}(t) = \sum_{i=1}^{r} \sum_{j=1}^{r} \mu_i(\xi(t)) \mu_j(\xi(t)) \tilde{A}_{ij} \tilde{e}(t)
$$

(26)

In Takagi-Sugeno modeling, it is often considered that the premise variable $\xi(t)$ is the input, the output or the state of the system, which are necessarily affected by faults. Consequently, $\xi(t) \neq \xi_f(t)$. In addition, if $\xi_f(t)$ is measurable, the state estimation error and the state tracking error are expressed by (23). Now, with these considerations, when $\xi(t) = u(t)$ and $\xi_f(t) = u_f(t)$, the term $\delta(t)$ does not converge to zero if $x_f(t)$ converges to the reference state $x(t)$ but if $\xi(t) = y(t)$ and $\xi_f(t) = y_f(t)$, the tolerant control allows the convergence of $x_f(t)$ to $x(t)$ and $y_f(t)$ to $y(t)$, then the term $\delta(t)$ converges also to zero which gives better results compared to the case where $\xi(t) = u(t)$. The same problem can appear if the output is also affected by faults. In these cases, the fault tolerant control design aims to minimize the difference between $x_f(t)$ and $x(t)$ and to minimize the $L_2$ gain of the transfer from $\delta(t)$ to the state tracking error.

B. Fault tolerant control design

The gains $K$, $H_{1i}$, and $H_{2i}$ are determined by solving the optimization problem under LMI constraints given in theorem 1.

**Theorem 1:** Consider $\lambda$ a positive scalar. The system (23) that generates the state tracking error $e(t)$ and the state and fault estimation errors $e_a(t)$ is stable and the $L_2$-gain of the transfer from $\delta(t)$ to $e_a(t)$ is bounded if there exists symmetric and positive definite matrices $X_1$, $X_2$, $P_2$ and $P_3$, matrices $H_i$ and $K$ and positive scalars $\gamma$ solution to the following optimization problem

$$
\min_{X_1, X_2, P_2, K, H_i} \gamma \quad \text{s.t.} \quad (4) - (5)
$$

where

$$
Y_{ij} = \begin{pmatrix} \Psi_i & -B_i M & 0 & I_n & X_1 \\ * & -2\lambda X & M & 0 & 0 \\ * & * & \Delta_{ij} & 0 & 0 \\ * & * & * & -\gamma I_n & 0 \\ * & * & * & * & -I_n \end{pmatrix} < 0
$$

(27)

$$
\Psi_i = A_i X_1 + X_1 A_i^T - B_i \tilde{K} - \tilde{K}^T B_i^T
$$

(28)

$$
\Delta_{ij} = P_2 \tilde{A}_i + \tilde{A}_i^T P_2 - \tilde{H}_i \tilde{C}_j - \tilde{C}_j^T \tilde{H}_i^T
$$

(29)

$$
M = \begin{pmatrix} K & X_2 \end{pmatrix}, \quad X = \begin{pmatrix} X_1 & 0 \\ 0 & X_2 \end{pmatrix}
$$

(30)

The controller gains and those of the observer are computed from

$$
H_i = \begin{pmatrix} H_{1i} \\ H_{2i} \end{pmatrix}, \quad K = \tilde{K} X_1^{-1}
$$

(31)

and the attenuation level of the transfer from $\delta(t)$ (19) to $e(t)$ (17) is obtained by

$$
\gamma = \sqrt{\gamma}
$$

(32)
The time derivative of the function \( V(\dot{e}(t)) \) is given by

\[
\dot{V}(\dot{e}(t)) = \sum_{i=1}^{r} \sum_{j=1}^{r} \mu_i(\xi_f(t))\mu_j(\xi_f(t))\dot{e}(t)^T \mathcal{M}_{ij} \dot{e}(t)
\]

where

\[
\mathcal{M}_{ij} = \xi \begin{pmatrix} \Lambda_{ij} & -P_i \tilde{L}_i \\ 0 & P_j \tilde{A}_j - P_j H_j \tilde{C}_j \end{pmatrix}
\]

and

\[
\Lambda_i = P_i A_i - P_i B_i K
\]

and \( \xi \) is a function defined in the notation 1.

In addition, the term \( \dot{\delta}(t) \) depends on \( x(t), u(t) \) which are bounded, then it is also bounded. So, the objective is to minimize the \( L_2 \)-gain of the transfer from \( \dot{\delta}(t) \) to the state tracking error \( e(t) \), this is formulated by

\[
\|e(t)\|_2 < \gamma, \quad \|\dot{\delta}(t)\|_2 \neq 0
\]

Then, we are seeking to ensure asymptotic convergence toward zero if \( \dot{\delta}(t) = 0 \) and to guarantee a bounded \( L_2 \)-gain if \( \dot{\delta}(t) \neq 0 \). This problem can be formulated as follows

\[
\dot{V}(\dot{e}(t)) + e(t)^T \dot{e}(t) - \gamma^2 \dot{\delta}(t)^T \dot{\delta}(t) < 0
\]

By replacing the expression of \( \dot{V}(\dot{e}(t)) \) (35), in inequality (39) and after some calculation we obtain that the inequality (39) is negative if the following conditions hold

\[
N_{\xi_f \dot{\xi}_f} = \sum_{i=1}^{r} \sum_{j=1}^{r} \mu_i(\xi_f(t))\mu_j(\xi_f(t))N_{ij} < 0
\]

where

\[
N_{ij} = \begin{pmatrix} \xi (A_i + I_n) & -P_i \dot{L}_i & P_i \\ 0 & \xi (P_j \tilde{A}_j - P_j H_j \tilde{C}_j) & 0 \\ P_i & 0 & -\gamma^2 I \end{pmatrix}
\]

with the congruence lemma, we obtain

\[
N_{\xi_f \dot{\xi}_f} < 0 \iff WN_{\xi_f \dot{\xi}_f}W^T < 0
\]

with

\[
W = \begin{pmatrix} P_1^{-1} & 0 & 0 \\ 0 & X & 0 \\ 0 & 0 & I \end{pmatrix}, \quad X = \begin{pmatrix} P_1^{-1} & 0 & 0 \\ 0 & X_2 & 0 \end{pmatrix}
\]

\( X_2 \) is symmetric and positive definite matrix. The following is then obtained

\[
\sum_{i=1}^{r} \sum_{j=1}^{r} \mu_i(\xi_f(t))\mu_j(\xi_f(t)) \begin{pmatrix} \Xi_i & -\tilde{L}_i & 0 \\ * & X \Delta_{ij} X & 0 \\ * & * & -\gamma^2 I \end{pmatrix} < 0
\]

where

\[
\Xi_i = A_i P_1^{-1} + P_1^{-1} A_i^T - B_K P_1^{-1}
\]

\[
\Delta_{ij} = P_2 \tilde{A}_i + \tilde{A}_i^T P_2 - P_2 H_i \tilde{C}_j - \tilde{C}_j^T H_i^T P_2
\]

The negativity of (44) imposes the negativity of \( \Delta_{ij} \) which can be analyzed using the following property

\[
(X + \lambda \Delta_{ij})^T \Delta_{ij} (X + \lambda \Delta_{ij}) \leq 0
\]

\[
\iff X \Delta_{ij} X \leq -\lambda (X + X^T) - \lambda^2 \Delta_{ij}^{-1}
\]

Consequently, (44) can then be bounded in the following way

\[
Y_{\xi_f \dot{\xi}_f} = \sum_{i=1}^{r} \sum_{j=1}^{r} \mu_i(\xi_f(t))\mu_j(\xi_f(t))Y_{ij} < 0
\]

where

\[
Y_{ij} = \begin{pmatrix} \Xi_i & -\tilde{L}_i & 0 \\ * & -2X & \lambda I & 0 \\ * & * & \Delta_{ij} & 0 \\ * & * & * & -\gamma^2 I \end{pmatrix}
\]

After the use of the lemma 1, in order to express the inequalities in linear form with respect to \( P_1^{-1}, P_2, K, \) and \( H_i \), the following change of variables are used

\[
X_1 = P_1^{-1}, \quad \tilde{K} = K X_1, \quad \tilde{H}_i = P_2 H_i, \quad \gamma = \gamma^2
\]

In addition

\[
\tilde{L}_i X = B_i \begin{pmatrix} K & I \end{pmatrix} X = B_i \begin{pmatrix} \tilde{K} & X_2 \end{pmatrix}
\]

Then, the relaxed stability conditions satisfying the attenuation level of the \( L_2 \) gain of the transfer from \( \dot{\delta}(t) \) to the state tracking error \( e(t) \), given in theorem 1, are obtained.

Remark 2: The assumption that the fault signal is constant over the time is restrictive, but in many practical situations where the faults are slowly time-varying signals, the estimation of the faults is correct, and the proposed FTC scheme can be applied. In the case where the faults are not slowly time-varying or constant, the Proportional Integral Observer (PIO) can be replaced by a Proportional Multiple Integral Observer (PMIO). Such is able to estimate a large class of time-varying signals which satisfies the assumption \( f^{(q+1)} = 0 \). The principle of this observer is based on the estimation of all the \( q^b \) derivatives of the signal \( f(t) \). This observer can also be extended to the case where \( f^{(q+1)} \) is bounded (see [8]).

III. Simulation example

To illustrate the proposed actuator fault tolerant control strategy for T-S systems with measurable premise variables affected by the faults, we proposed two academic examples.
A. First case: $\xi(t) = u(t)$

Consider the T-S system described by

$$\begin{cases}
\dot{x}_f(t) = \sum_{i=1}^{5} \mu_i(u(t)) (A_1 x_f(t) + B_1 u_f(t) + B_i f(t)) \\
y_f(t) = C x_f(t)
\end{cases}$$

where

$$A_1 = \begin{bmatrix} -2 & 1 & 1 \\ 1 & -3 & 0 \\ 2 & 1 & -8 \end{bmatrix}, \quad A_2 = \begin{bmatrix} -3 & 2 & -2 \\ 0 & -3 & 0 \\ 5 & 2 & -4 \end{bmatrix}.$$ $$B_1 = \begin{bmatrix} 0 \\ 1 \\ 1 \end{bmatrix}, \quad B_2 = \begin{bmatrix} 1 \\ 1 \\ 0 \end{bmatrix}, \quad C = \begin{bmatrix} 1 & 1 & 1 \end{bmatrix}$$

The weighting functions depend on the input $u(t)$ which is the nominal control of the system in the fault-free case; they are defined by $\mu_1(u(t)) = (1 - u(t))/2$ and $\mu_2(u(t)) = 1 - \mu_1(u(t))$. To apply the proposed FTC strategy, the following reference model is considered

$$\dot{x}(t) = \sum_{i=1}^{5} \mu_i(u(t)) (A_1 x(t) + B_1 u(t)), \quad y_f(t) = C x(t)$$

The fault $f(t)$ is time varying and defined as follows

$$f(t) = \begin{cases}
-u(t) & t \geq 10 \\
0 & t < 10
\end{cases}$$

Notice that even if the assumption $\dot{f}(t) = 0$ is not satisfied, the PIO is able to reconstruct time varying signals with slow variation.

To increase the observer performances, a pole assignment is performed in $\{z | \Re(z) < -14, |z| < 20\}$ in order to enhance the convergence speed of the state estimation errors toward zero and to reduce the oscillatory phenomenon.

Solving the optimization problem under LMI constraints in theorem 1 with $\lambda = 20$, results in the following matrices

$$H_{11} = \begin{bmatrix} -24.84 & 59.47 \\ 30.05 & -29.75 \\ 31.54 & -43.02 \end{bmatrix}, \quad H_{12} = \begin{bmatrix} -11.03 & 45.34 \\ 31.58 & -33.25 \\ 17.80 & -26.5 \end{bmatrix}$$

$$H_{21} = \begin{bmatrix} 337.82 & -356.67 \end{bmatrix}, \quad H_{22} = \begin{bmatrix} 338.57 & -353.93 \end{bmatrix}$$

$$K = \begin{bmatrix} 6.5179 & 4.9204 \\ 1.2659 \end{bmatrix}, \quad \gamma = 0.4721$$

The figure 2 (top) shows the time evolution of the fault $f(t)$ and its estimate $\hat{f}(t)$, while the bottom part depicts the nominal control $u(t)$ and the FTC $u_f(t)$. The state estimation errors, $x_f(t) - \dot{x}_f(t)$ are shown in the top of figure 3, while the bottom part shows the state tracking errors $x(t) - x_f(t)$. Finally, figure 4 allows the comparison of the reference model states with the state obtained when the system is faulty without any modification of the control law and those of the system when using FTC.

Even if a fault occurs, the system trajectory follows the trajectory of the reference model which represents the trajectory of the system in the fault-free situation. Thus, the FTC control law compensates the fault and allows a normal functioning of the system in the presence of faults.

B. Second case: $\xi(t) = y(t)$

In this subsection, the previous system is considered, but with weighting functions depending on the first component of the system output vector. The figure 5 illustrates the state estimation errors (top) and the state tracking errors (bottom).
It is clear that the use of weighting functions depending on the output of the system provides better results than the case where they are depending on the control input.

This is due to the fact that the system is only affected by actuator faults and the perturbation term \( \delta(t) \) converges to zero when \( y_f(t) \) converges to the reference \( y(t) \). But in the previous simulation, the term \( \delta(t) \) did not converge to zero, in the presence of fault, because \( u(t) \neq u_f(t) \) which leads to \( \mu_i(u(t)) \neq \mu_i(u_f(t)) \). As a conclusion, considering the problem of fault tolerant control of T-S systems with actuator faults, it is more interesting to use the output of the system as a premise variable. However, in the simultaneously occurring actuator and sensor faults, better results are obtained by using the state of the system as a premise variable, this is more difficult and general case but the obtained state error tracking is less than ones obtained above, first results on this point are submitted in [9].

IV. CONCLUSION

This paper is dedicated to the design of an active fault tolerant control law for nonlinear Takagi-Sugeno systems. A reference model is used and the proposed control law is then designed for guaranteeing the convergence of the states of the system to the states of a reference model even if fault occurs. This control law uses the nominal control input developed for the system in fault-free case and two additional terms related to the estimated fault and the trajectory tracking error. The stability is studied with the Lyapunov theory and \( L_2 \) optimization. The LMI formalism is used in order express stability conditions in term of linear matrix inequalities. Future works will be devoted to the study of the case when the weighting functions depend on unmeasurable variables as the system state. Indeed, the interest of this case is the possibility to deal with simultaneous actuator and sensor faults. In addition, it could be interesting to develop the FTC law by taking into account modeling uncertainties and some external perturbations.
